SUMMARY

This report describes a suite of programs to be used for management of a Signal Measurement Data Base (SMDB). The programs permit a user to write on disk, from tape, files of seismic signal measurements which have been used, for example, in VELA-sponsored identification experiments. The program suite consists of software to establish the SMDB and to enable user interface with the data base. Moreover, the structure of the SMDB is also presented here to illustrate its expandable and maintainable format.

SECTION I
INTRODUCTION

The purpose of the Data Base Transfer (Task 4.3.1 under Contract Number F08606-79-C-0014) is to transfer the Event Discriminant Data Base from the PDP-15/50 to the PDP-11/70, and to do so under the following constraints:

- Preserve the signal measurements for all event-stations processed under Contract Number F08606-79-C-0014.
- Establish an expandable and maintainable Signal Measurement Data Base (SMDB) on the PDP-11/70 that:
  - satisfies the first constraint above
  - may be updated with additional signal measurements for event-station data processed by other contractors.
- Provide FORTRAN-compatible software utilities to:
  - initialize the SMDB Directory and Free-Block File
  - update the SMDB by event, station, measurement, or contractor
  - access the SMDB for information by event, station, measurement, or contractor.
- Write selected driving programs to demonstrate an:
  - SMDB update with signal measurements discussed in the first criterion
  - SMDB access to list Directory information and signal measurements

- SMDB access to compute unbiased network averages of signal measurements for a specified event.

- Demonstrate this software contingent on the availability of UNIX operating system utilities provided by the Government.

Section II of the report describes the detailed structure of the SMDB. Section III discusses the establishment of the SMDB, utilizing signal measurements for all event-station data processed under Contract Number F08606-79-C-0014. Section IV presents conclusions and recommendations for future work. Finally, documentation of the software utilities developed during the task is provided in Appendix A of this report, while listings of the software may be found in Appendix B. Appendix C contains a description of ENSCO's raw signal measurement tape format.

SECTION II
STRUCTURE OF THE SIGNAL MEASUREMENT DATA BASE (SMDB)

The Signal Measurement Data Base (SMDB) uses a multi-file structure which is designed and implemented in FORTRAN IV for the PDP-11/70. The principal items comprising the SMDB are vectors of signal measurements obtained by preprocessing waveform data from various recording stations. The design of the data base was predicated on the following criteria:

- Expandability with respect to events, stations, and measurements.
- Allocations for data from up to four contractors.

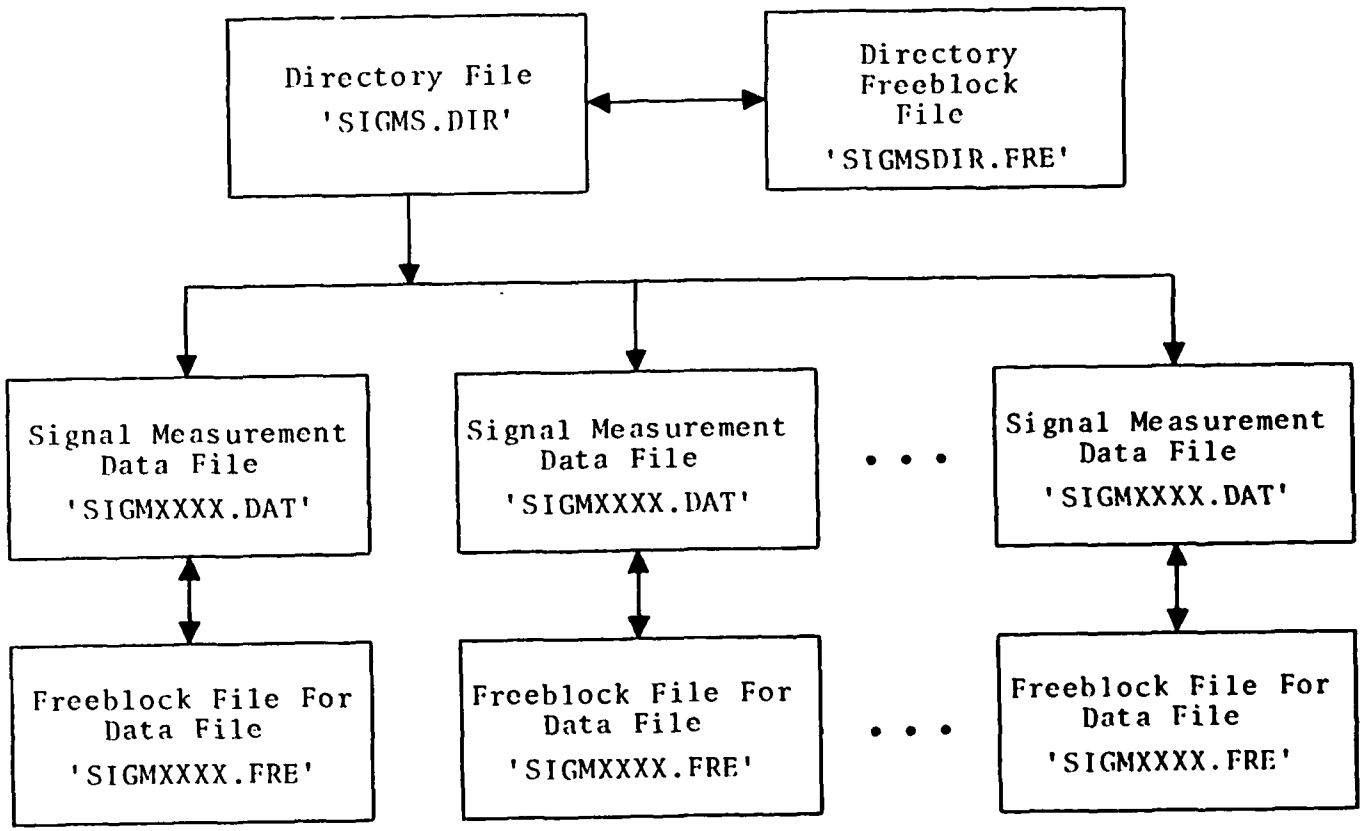
To this end, a linklist structure was employed in organizing the data.

The SMDB consists of four types of files:

- A Directory File (SIGMS.DIR).
- A Directory Freeblock File (SIGMSDIR.FRE).
- Signal Measurement Data Files (one file for each event).
- Freeblock File for Data Files (one file for each event).

The general organization of the SMDB is shown in Figure II-1.

The directory file, SIGMS.DIR, consists of a header record followed by Event Base Vectors and Station Entry Vectors. These vectors are for sorting and retrieving event/



Note: A signal measurement data file and its associated freeblock file exist for each event. File names are as shown with the event designation number substituted for the characters XXXX.

FIGURE II-1

ORGANIZATION OF THE SIGNAL MEASUREMENT DATA BASE (SMDB)

signal information. The header record contains the following information:

- The current number of events in the system.
- The record number of the first event entry.
- The current number of directory records that are in use.
- The maximum number of directory records allowed.

All entries are allocated four bytes of storage.

The structure of the Event Base Vector and Station Entry Vector are shown in Figure II-2. Each entry record is 128 bytes long and consists of thirty-two four-byte words. The attributes of the Event Base Vector are defined as follows:

- Event Sequence Number - A virtual integer J, where $1 \leq J \leq$ # of events, which indicates the order an event appears in the directory. For example, the fifth event listed in the directory has an event sequence number of 5. The sequence number for an event changes when the SMDB is updated with new events.
- Event Designation Number - A unique four-digit number appearing as the last four characters of the ENSCO-alphanumeric event designation.
- Event Origin Time - Source time in YY DDD HH MM SS (5 word integer format).
- Event Latitude - Source latitude in degrees, N(+), S(-).
- Event Longitude - Source longitude in degrees, E(+), W(-).
- Event m_b - Event bodywave magnitude.

EVENT BASE VECTOR

Event Sequence Number (Virtual)	Event Designation Number	Event Origin Time	Event Latitude $+N^{O}$	Event Longitude $+E^{O}$	Event m_b	Event Depth	Unused (22*4 words)	Backward Pointer To Last Event	Forward Pointer To Next Event	Total Number Of Stations	Pointer To First Station

STATION ENTRY VECTOR

Station Name	Station Number	Unused (15*4 words)	Backward Pointer To Last Station	Forward Pointer To Next Station	Total Number Of Contractors	Contractor Name	First Measurement Record	Number Of Measurements	. . .	. . .	. . .

FIGURE II-2
DIRECTORY ENTRIES

- Event Depth - Source depth in km.
- Backward Pointer to Last Event - The record number corresponding to the previous event base vector (zero if first event).
- Forward Pointer to Next Event - The record number corresponding to the next event base vector (zero if last event).
- Total Number of Stations - The total number of station entry vectors for the event. This corresponds to the total number of unique stations for which measurements are available for a given event.
- Point to First Station - The record number corresponding to the first station entry vector for the event.

The attributes of the Station Entry Vector are defined as follows:

- Station Name - The four-character ENSCO-alphanumeric station designation.
- Station Number - The integer number K, $1 \leq K \leq 50$, assigned to a given station.
- Backward Pointer to Last Station - The record number corresponding to the last station entry vector (zero if first station).
- Forward Pointer to Next Station - The record number corresponding to the next station entry vector (zero if last station).
- Total Number of Contractors - The total number of contractors contributing signal measurements for an event-station (maximum of four).

- Contractor Name - The four-character alphanumeric designation for a contributor to the data base.
- First Measurement Record - The record number in the signal measurement data file corresponding to the first record of signal measurements.
- Number of Measurements - The total number of measurement values contributed by the associated contractor.

Both the event base vectors and the station entry vectors have unused locations where, if desired, additional information can be stored.

The directory freeblock file, SIGMSDIR.FRE, consists of a header record containing the current number of non-sequential free records in the directory file. This header record is followed by records consisting of 256 four-byte words. These records each contain up to 256 record numbers. The function of this freeblock is to allow the reuse of records freed by the deletion of entries in the directory file. This practice minimizes the size of the directory file.

Each event has one signal measurement file with a name of the form SIGMXXXX.DAT, where XXXX is the event designation number. The records in these files consist of 64 four-byte words. Two types of records make up the data file: a header record and data records (multiple). The header record contains the current number of data records in use and the maximum number of data records allowed in the first two positions. The structure of the data records is shown in Figure II-3. The major attributes are defined as follows:

31 Measurement Values (4 * byte word)	31 Measurement Labels (4 * byte word)	Last Measurement Record	Next Measurement Record

(file name of form 'SIGMXXXX.DAT' where XXXX=Event Designation Number)

FIGURE II-3

STRUCTURE OF DATA RECORD IN SIGNAL MEASUREMENT DATA FILE

- Measurement Value - A signal parameter obtained by preprocessing waveform data from various recording stations. In the present case, the measurements are ordered into four categories depending on the type of data from which the discriminants are derived (namely, long-period signals/noise, short-period regional signals/noise, short-period teleseismic signals/noise, and short-period signals/noise).
- Measurement Labels - A four-character alphanumeric designation associated with each measurement value. This label is used as a keyword in locating a given signal parameter.
- Last Measurement Record - The record number corresponding to the last data record associated with a given contractor (zero if first record).
- Next Measurement Record - The record number corresponding to the next data record associated with a given contractor (zero if last record).

Each event also has a freeblock file associated with its signal measurement file. The files are named analogously to the data file. The file name is of the form SIGMXXXX.FRE, where XXXX is the event designation number. The structure and function of this file are the same as those of the directory freeblock file.

SECTION III
ESTABLISHMENT OF THE SMDB

The SMDB is established by executing DDBASE. This routine takes a labeled 1600 bpi 9-track signal measurement tape as input. The data headers for each event-station file should follow the description in Table III-1*. Before DDBASE is initially run, the program INITIAL must be executed. This program initializes the directory files of the data base and deletes any data files that may be present. In general, the UNIX command SMT must also be performed with the appropriate options before any execution of DDBASE. These routines along with other support routines and subroutines are documented in Appendix A. The source file names and the names of the associated source files and libraries (if any) are also provided. The algorithms can be executed by following the standard UNIX FORTRAN guidelines. Appendix B contains compiled listings of the data base management and demonstration programs.

---

* The conversion of the data header from the standard ENSCO format (see Appendix C) is performed by the IBM 360/44 program COPY99.

375	A	Not used.

SECTION IV
CONCLUSIONS AND RECOMMENDATIONS

An expandable and maintainable Signal Measurement Data Base (SMDB) program suite has been designed and compiled on the PDP-11/70 under the UNIX operating system. Tapes (from the SDAC) which were used in the VELA-sponsored identification experiment, and which were used in the development and test of the SMDB program suite, are:

1. L22882 (IBM 360/44)
2. L13033 (DEC PDP-15/50).

These tapes can be used in future efforts to refine the SMDB program suite.

It should be noted that several problems were encountered with the UNIX FORTRAN compilers during attempts to implement the SMDB routines. Specifically, the routines were initially coded in a modified version of DEC RT-11 FORTRAN IV (Rottman, 1975). (The UNIX command to request this compiler is FORTRAN.) Difficulties encountered with this compiler included problems which are apparently related to array size and to the argument lists. That is, a routine could be made to generate routine errors, or not to do so, by increasing or decreasing the size of its arrays, respectively. Associated error messages, in general, indicated a bus error or a segmentation violation. Regardless, a solution to this problem was not readily apparent. Further, the number of

arguments in a subroutine argument list appeared to be limited to eight. Any additional arguments were not passed. It was possible to circumvent this problem by passing arguments in a named common block.

Toward the end of this task, a new FORTRAN compiler was provided (Anon., 1978). This compiler is based on American National Standard (ANS) FORTRAN 77. (The UNIX command to request this compiler is F77.) An investigation was made into the feasibility of converting the SMDB routines to the FORTRAN 77 standard. Necessary changes would include substitution of the ENCODE/DECODE statements with equivalent statements, modification of the file I/O, modification of character variables, and modification of the code to allow for irregularities in the new compiler. ENCODE/DECODE statements can be replaced with 'reads' and 'writes' to internal files. This replacement is not possible on a one-to-one basis, and some additional program structuring will be necessary to provide for parallel operations. The file I/O initiated using the routines SETFIL and DFILE does not appear to be equivalent to using SETFIL and DEFINE FILE in the original compiler. In particular, it seems that the file to be accessed must already exist in order to be accessed (i.e., the system does not create a new file). This was not the case with the compiler called using FORTRAN. Another difference in file I/O requirements was that the last record written in a file could not be read subsequent to the write to the file. This difficulty may indicate that it is necessary to close and open the file between write and read operations. An example of one irregularity encountered during the investigation of the F77 compiler is the failure to

compile a logical expression with a unary minus (e.g., if (IFLG.EQ.-1) go to 100). The same logical expression without the minus sign, however, does compile.

The results of the investigation made indicate that the F77 compiler is sufficiently different from the FORTRAN compiler as to require a significant effort to convert the SMDB from the FORTRAN to the F77 compiler. It will first be necessary to establish the operating characteristics of the new compiler (i.e., the logic sequences necessary to accomplish a given operation). After the methods for performing the desired operations have been established (usually done by the trial-and-error method), the SMDB routines can be restructured (i.e., converted).

At this time, a competent FORTRAN language compiler is not available on the SDAC PDP-11/70. Note, however, that the use of the FORTRAN language is not recommended by the designers of the UNIX operating system for major applications using UNIX.

As a final comment, several additional routines could be added to make the SMDB more versatile. These include a function to delete event and/or station entries and a function to modify individual measurements resident in the data base. The design of the SMDB included consideration of these avenues for development. Several of the routines documented in Appendix A could be used to implement these options.

APPENDIX A
DOCUMENTATION OF SIGNAL MEASUREMENT DATA BASE (SMDB) ROUTINES

This appendix contains descriptions of the main routines and associated subroutines used to manage and demonstrate the SMDB. These descriptions include definitions of arguments, commons, and data types. Comments on the use of the routines are also provided. Applicable source files resident on the PDP-11/70 system are listed.

These routines can be incorporated into additional algorithms to manipulate the SMDB. Several examples of this type of application are generation of files of unbiased network magnitude measurements, computation of discriminants, and classification of events.

Subroutine:

ACCESS

Arguments:

(NDSG, STAT, CONTR, MSLAB, NRET, RMEAS, RLAB, IEVR).
NDSG - integer * 4
STAT - real * 4
CONTR - real * 4
MSLAB - real * 4
NRET - integer * 4
RMEAS - real * 4 array of length $\geq$ NRET
RLAB - real * 4 array of length $\geq$ NRET
IEVR - integer * 4

Commons:

COMMON/FLAGS/IFLGMS, IFLGEV
IFLGMS - integer * 2
IFLGEN - integer * 2
COMMON/ASVAR/NXREC1, NXREC2, NXREC3, NXREC4

Description:

ACCESS accesses the signal measurement data base and returns the measurements.

NDSG is an event designation number.

STAT is a four-character station name (if it is ****, the given measurement is returned for all stations reporting the event).

CONTR is a four-character contractor name.

MSLAB is a four-character measurement label.

NRET is the number of measurements returned.

RMEAS contains the measurements to be returned.

RLAB contains the measurement labels when IFLGMS=0.

IEVR is the event record number in the directory file SIGMS.DIR.

IFLGMS = { 0, returns all measurements for the given station (in RMEAS) with the associated labels (in RLAB) — WARNING: it should be noted that there is no guarantee that all of the measurements will be in order (or exist) across stations.
1, return only indicated measurement for the given station.

IFLGEV = { 0, search for event
1, use event record number in IEVR.

NXREC1, NXREC2, NXREC3, NXREC4 are the associated variables for the maximum of four data base files open at one time.

Restrictions:

1) The event data file is opened on logical unit number 2.
2) It is assumed that the directory file SIGMS.DIR is already open on logical unit number 1.

Source File:

access.for

Associated Source File:

search.for

Subroutine:

CHKFRE

Arguments:

(LUNIT, IFLAG, NFB, IFREC).
LUNIT - integer * 2
IFLAG - integer * 2
NFB - integer * 4
IFREC - integer * 4

Commons:

COMMON/ASVAR/NXREC1, NXREC2, NXREC3, NXREC4
all variables integer * 2

Description:

CHKFRE checks the indicated freeblock file and either returns a free record number of extends the freeblock file. The file is modified accordingly and the total number of freeblocks before the call is returned.

LUNIT is the logical unit number associated with the freeblock file (in practice LUNIT=3 is the freeblock file for the directory and LUNIT=4 is the freeblock file for the event data file.

IFLAG { 0, returns free record number in IFREC
1, freeblock extended with record number in IFREC.

NFB is the number of freeblocks prior to a call.

IFREC is the free record number.

NXREC1, NXREC2, NXREC3, NXREC4 are the associated variables for all possible open data base files.

Restrictions:

1) The appropriate freeblock files must be open on logical unit LUNIT.

Source File:

chkfre.for

Main Routine:

COPY99

Input:

Signal measurement tape in standard ENSCO format.

Description:

COPY99 is an IBM 360/44 program used to convert the data headers of the signal measurement tape to the format expected by the PDP-11/70 program DDBASE and output the results to another tape. The output tape is input to the signal measurement data base management routines. Prior to execution of this program, the character string 'NSKIP' should be changed to the number of data files to skip on the input tape before starting the conversion and copy. The input tape is accessed on unit 8 and the output tape is accessed on unit 9.

Main Routine:

DDBASE

Input:

9-track signal measurement tape with appropriate EBCDIC data headers on logical unit 0.

Description:

DDBASE accesses the information on a labeled 1600 bpi 9-track signal measurement tape and performs the necessary conversions and formating before providing the information to sub routine UPDATE. This routine includes a look-up table for station names based on the station number, a look-up table for measurement labels, EBCDIC to ASCII conversion, and IBM 360/44 to PDP-11/70 floating-point conversion.

Restrictions:

1) The 9-track input tape must have the correct EBCDIC header.
2) All information for an event on a tape must be consecutive.
3) UNIX command smt must be performed before execution of DDBASE with the appropriate options.
4) The algorithm currently requires the tape to be mounted on unit 0 (allowable units are 0-7).

Source File:

ddbase.for

Associated Source Files:

update.for
search.for
chkfre.for

Program Source File:

ddbasep.for

Associated libraries (in addition to normal FORTRAN library):

/lib/f4u

Main Routine:

EVLIST

Input: (from terminal)

Logic flag (IFLG) (requested inputs 0 or 1) range of event sequence numbers (virtual).

Description:

EVLIST displays the event-station information stored in the data base in the form requested by the input parameters.

If a zero input for the logic flag the event information and the stations reporting are displayed.

If a one is input the individual station measurements for contractor ENSC are included.

Source File:

evlist.for

Associated Source Files:

search.for
access.for

Program Source File:

evlistp.for

Main Routine:

INITIAL

Description:

INITIAL initializes the signal measurement data base. This is accomplished by deleting all existing event data files (if any) and by initializing the header records of the directory file (SIGMS.DIR) and its freeblock file (SIGMSDIR.FRE).

Program Source File:

initial.for

Subroutine:

MBIAS

Arguments:

(RMX, NSTA, NDISC, DISCR).

RMX - real * 4 of length $\geq$ NSTA * NDISC.

NSTA - scalar (integer * 2).

NDISC - scalar (integer * 2).

DISCR - real * 4 array of length $\geq$ NDISC.

Description:

MBIAS performs Ringdal's maximum likelihood estimation of event magnitude (Ringdal, 1975) using signal and noise measurements.

RMX is a matrix whose elements contain signal or noise measurements, or a flag indicating that the element is to be ignored.

$$RMX_{ij} = \begin{cases} \text{signal measurement} + 1000 \\ \text{noise measurement} - 1000 \\ 0 \text{ if it is to be ignored.} \end{cases}$$

NSTA is the number of stations.

NDISC is the number of measurements per station.

DISCR contains the unbiased magnitude estimates.

Restrictions:

1) RMS contains the measurements for station 1 followed by the measurements for station 2, etc. until the measurements for station NSTA have been stored.

2) NSTA must be ≤ 50.

Source File:

mbiascat.for

Main Routine:

NAVE and (NAVE2)

Input: (from terminal)

Event designation number.

Description:

NAVE and NAVE2 are drivers to demonstrate the subroutine MBIAS. The unbiased network averages are computed for several measurements for the designated event.

Source File:

nave.for and nave2.for

Associated Source Files:

mbiascat.for
search.for
access.for

Program Source File:

navep.for

Main Routine:

RETURN

Input: (from terminal)

Event designation number
Station name
Measurement label.

Description:

RETURN is a debugging routine to test subroutines ACCESS and SEARCH. Various measurements are returned depending on the input parameters and the setting of flags hardwired into the program.

Source File:

return.for

Associated Source Files:

search.for
access.for

Program Source File:

returnp.for

Subroutine:

SEARCH

Arguments:

(IFLAG, KEY, EVREC, STREC, ICON, MSREC, MSIND, ISRCH)
IFLAG - integer * 2
KEY - four word real * 4 array
EVREC - integer * 4
STREC - integer * 4
ICON - integer * 4
MSREC - integer * 4
MSIND - integer * 2
ISRCH - integer * 2

Commons:

COMMON/ASVAR/NXREC2, NXREC2, NXREC3, NXREC4
all variables INTEGER * 2.

Description:

SEARCH searches the signal measurement data base for a match to a specific keyword and returns the appropriate record number and index (if applicable).

IFLAG =
- 0, full search for a given measurement (needs all keywords)
- 1, search for event designation number
- 2, search for station name (needs evrec)
- 3, search for contractor name (needs strec)
- 4, search for measurement (needs icon) (returns record number in 'sigmxxxx.det' file and the index into the record).

KEY is the four-word array containing the keywords

KEY(1) = event designation number (should be converted to floating point prior to call)

KEY(2) = four-character station name

KEY(3) = four-character contractor name

KEY(4) = four-character measurement label.

EVREC is the event record number in the directory file, SIGMS.DIR.

STREC is the station record number in the directory file, SIGMS.DIR.

ICON is the index into the station record of the contractor block - possible values are 21, 24, 27, and 30.

MSREC is the measurement record number in the event data file SIGMXXX.DAT.

MSIND is the index into the measurement record of the measurement value

ISRCH is an error flag

$$ISRCH = \begin{cases} 0, & \text{successful search} \\ 1, & \text{unsuccessful search} \end{cases}$$

NXREC1, NXREC2, NXREC3, NXREC4 are the associated variables of all possible open data base files.

Restrictions:

1) If EVREC or STREC are equal to zero when IFLAG=2 or 3, respectively, the program is stopped. This also occurs if the number of stations or measurements is zero.

2) The content of KEY(1) must be in floating point representation.

3) The directory file SIGMS.DIR must be open on logical unit number 1 and the event data file must be open on logical unit number 2.

search.for

Subroutine:

UPDATE

Arguments:

(IERR)
IERR - integer * 2

Commons:

COMMON/ARG/ESINFO
ESINFO - 141-word real * 4 array
common/ASVAR/NXREC1, NXREC2, NXREC3, NXREC4
all variables integer * 2

Description:

UPDATE establishes the signal measurement data base given the pertinent event-station information and flags contained in array ESINFO.

IERR is an error flag.

IERR = {0, no errors
1, error in establishing data base.

ESINFO is the information packet passed to this data base routine.

ESINFO(1) = event designation number (integer * 4).
ESINFO(2) = bbYY
ESINFO(3) = bDDD
ESINFO(4) = bbHH
ESINFO(5) = bbMM
ESINFO(6) = bbSS
} event origin time (integer * 4).
ESINFO(7) = event latitude ($\pm 90^{o}$N)(represented as F8.3 in this data base).

ESINFO(8) = event longitude (+180°E) (represented as F8.3 in this data base).

ESINFO(9) = event magnitude (m_b) (represented as F4.2 in this data base).

ESINFO(10) = depth of event (integer * 4).

ESINFO(11) = event flag IFLGEV (integer * 4).

ESINFO(12) = four-character station name.

ESINFO(13) = station number (integer * 4).

ESINFO(14) = station flag IFLGST (integer * 4).

ESINFO(15) = four-character contractor name.

ESINFO(16+(K-1)*2) = four-character measurement label K=1,62.

ESINFO(17+(K-1)*2) = associated measurement value K=1.62.

ESINFO(140) = event record number in the directory file SIGMS.DIR (integer * 4).

ESINFO(141) = station record number in the directory file SIGMS.DIR (integer * 4).

IFLGEV (ESINFO(11)) is a flag that controls the logic flow of this routine in regard to events.

$$\text{IFLGEV} = \begin{cases} 1, & \text{search for event} \\ 0, & \text{add new event} \\ -1, & \text{update previous event (i.e., use event record number supplied in ESINFO(140)).} \end{cases}$$

IFLGST (ESINFO(14)) is a flag that controls the logic flow of this routine in regard to stations.

$$\text{IFLGST} = \begin{cases} 1, & \text{search for station} \\ 0, & \text{add new station} \\ -1, & \text{update previous station (i.e., use station record provided in ESINFO(141)).} \end{cases}$$

The following files are associated with the indicated logical units.

SIGMS.DIR (directory file) logical unit = 1.

SIGMXXXX.DAT (event data file, where XXXX is the event designation number) logical unit = 2.

SIGMSDIR.FRE (directory freeblock file) logical unit = 3.

SIGMXXXX.FRE (freeblock file for event data file) logical unit = 4.

NXREC1, NXREC2, NXREC3, NXREC4 are the associated variables for all possible open files.

Comments:

1) If an event is either flagged as new (i.e., not presently in the data base) or not found in a search, the station flag is set to zero to indicate that the stations are also new.
2) For the most efficient execution of this routine, the event-station information for a given event should be provided consecutively during a given run.
3) Update is written in such a way that measurements associated with an existing label can be replaced by the value in the information packet.
4) In general, the data base structure implemented by this routine is expandable with respect to events, stations, and measurements (linklist structure).

Restrictions:

1) The directory file must be open on logical unit 1 and the directory freeblock file must be open on logical unit 3.
2) Logical units 2 and 4 must be free.

3) The number of associated measurement labels and values must be ≤ 62. If the number is less than 62, the last measurement value must be followed by a word containing four blank characters.

APPENDIX B
LISTINGS OF SIGNAL MEASUREMENT DATA BASE (SMDB) PROGRAMS

This appendix contains compiled listings of various data base management and demonstration programs. They are COPY99, INITIAL, DDBASE, EVLIST, NAVE, and RETURN. A modified version of the main routine NAVE is also included as NAVE2.

APPENDIX C

FORMAT DESCRIPTION OF ENSCO'S RAW SIGNAL MEASUREMENT TAPE

FORMAT DESCRIPTION OF ENSCO'S RAW SIGNAL MEASUREMENT TAPE

The Raw Signal Measurement Tape is one of the tapes generated by the automated Signal Extraction Process of the Event Identification System (EIS) on the IBM 360/44 computer. This tape is a 1600 bpi nine-track tape and is written in the standard ENSCO format using physical I/O.

The standard nine-track tape format consists of a label file followed by one or more data files, followed by a trailer file. Each record in the data files represents a physical transfer of a specified number of bytes from program memory to magnetic tape. This results in efficient tape I/O and in a compact and easily interpreted tape. Figure C-1 illustrates the organization of the Raw Signal Measurement Tape. The individual components are described below.

The label file consists of two 80-byte records followed by an end-of-file mark (EOF). The first record is the IBM volume-serial header and begins with the characters VOL1. The second record is the ENSCO header and begins with the characters HDR1. The label file should be recognized by the IBM 360/44 as a standard tape label.

The data files each consist of a 1500-byte event header record followed by a 400-byte data record containing the raw signal measurements, followed by an end-of-file mark. A separate data file is generated for each event-station processed, and the data files are organized by site number (event header word 91). The stations corresponding to a given site number are presented in Table C-1 along with their locations and tectonic class.

40-50	Unassigned	-----	------	-

Table C-2 describes all possible event header entries. In this application, not all the entries in the header record are used. Entries in the header corresponding to seismic information for specific phases should be disregarded. Information pertaining to an event or a station, or to non-seismic data (i.e., data record length, etc.) is still meaningful.

Table C-3 defines the raw signal measurements present in the data record. The amplitude measurements (words 1-21) are corrected for distance using appropriate B-factors (Sax et al., 1978). In addition, the data entries have either +1000 or -1000 added to them to indicate whether the value is a signal measurement or a noise measurement, respectively. A zero entry indicates that no measurement is available for the corresponding quantity. No regional S or Lg data were processed for this data base.

Finally, the data files are followed by a trailer file containing one 80-byte record beginning with the characters EOIO. This record is followed by at least two consecutive end-of-file marks.

TABLE C-2

STANDARD EVENT HEADER DESCRIPTION
(PAGE 1 OF 7)

Words	Data Type*	Field
1	I	Seismogram number.
2	I	Number of components (1 or 3).
3	I	Edit length (time points).
4	F	Number of samples per second.
5	F	Edit start time (hours).
6	F	Edit start time (minutes).
7	F	Edit start time (seconds).
8-9	A	Array name.
10-12	A	Event designation.
13-14	A	Data type ('EDIT', 'GEN', or 'DISCR').
15	I	Data record length (bytes).
16	I	Number of edited sites.
17-18	A	Data partition ('SIGNAL' or 'NOISE')
19	A	Domain ('TIME' or 'FREQ').
20-21	A	Source routine.
22	A	Data orientation code ('RAW' or 'PBD')
23	I	Maximum number of channels processed.
24	I	Number of channels deleted.
25	F	Re-sample rate.
26	I	Edit start time (seconds into day).
27	I	Edit start time (year-day).

84	F	Elevation (Primary beam direction).
85	F	Source to Array Great Circle distance (degrees).
86	F	Source to Array Great Circle distance (km).
87-88	A	Seismometer type.
89	A	Recording type.
90	F	Estimated signal-to-noise ratio (dB).
91	I	Site Number.
92	F	Site latitude (± 90° N).
93	F	Site longitude (0-360° E).
94	I	Number of sub-arrays.
95-134	I	Index of the first sensor in each sub-array.
135-174	F	Reference sensor latitude (±90°N) for each sub-array.
175-214	F	Reference sensor longitude (0-360°E) for each sub-array.
215	A	Tectonic class code.

*A = Alphanumeric, I = Integer, F = Floating Point

TABLE C-2

STANDARD EVENT HEADER DESCRIPTION
(PAGE 5 OF 7)

Words	Data Type*	Field	
		Long-Period	Short-Period
216	F	Log_{10} of 50 second amplitude (vertical component).	S wave, LG (surface) wave, or regional P wave magnitude.
217	F	Log_{10} of 33 second amplitude (vertical component).	Teleseismic P wave magnitude.
218	F	Log_{10} of 25 second amplitude (vertical component).	Measured phase arrival time (seconds into edit) Value of 999999 indicates no detection.
219	F	Log_{10} of 20 second amplitude (vertical component).	Magnitude, from first envelope peak.
220	F	Log_{10} of 17 second amplitude (vertical component).	Mean smoothed frequency.
221	F	Log_{10} of 14 second amplitude (vertical component).	Maximum mean smoothed frequency.
222	F	Log_{10} of 12 second amplitude (vertical component).	Mean phase standard deviation.
223	F	Log_{10} of 50 second amplitude (transverse component).	Log_{10} of center frequency no. 1.
224	F	Log_{10} of 33 second amplitude (transverse component).	Log_{10} of center frequency no. 2.

*A = Alphanumeric, I = Integer, F = Floating Point

TABLE C-2

STANDARD EVENT HEADER DESCRIPTION
(PAGE 6 OF 7)

Words	Data Type*	Field	
		Long-Period	Short-Period
225	F	Log_{10} of 25 second amplitude (transverse component).	Log_{10} of center frequency no. 3.
226	F	Log_{10} of 20 second amplitude (transverse component).	Log_{10} of center frequency no. 4.
227	F	Log_{10} of 17 second amplitude (transverse component).	Log_{10} of center frequency no. 5.
228	F	Log_{10} of 14 second amplitude (transverse component).	Log_{10} of center frequency no. 6.
229	F	Log_{10} of 12 second amplitude (transverse component).	Log_{10} of center frequency no. 7.
230	F	Log_{10} of broadband A/T.	Log_{10} of center frequency no. 8.
231-238	F	Undefined.	Log_{10} of displacement at center frequencies no.1-8.
239	F	Undefined.	Broadband complexity.
240	F	Undefined.	Envelope complexity.
241-248	F	Undefined.	Instantaneous frequency complexity at center frequencies no. 1-8.
249	F	Undefined.	m_p (taken from first five seconds of data.

*A = Alphanumeric, I = Integer, F = Floating Point

TABLE C-2

STANDARD EVENT HEADER DESCRIPTION
(PAGE 7 OF 7)

Words	Data Type*	Field	
		Long-Period	Short-Period
250	F	Undefined.	Lg arrival time (seconds into day).
251-265	F	Variable-frequency detection ratios.	
266-267	A	Date on which data were edited.	
268	I	Start time of corresponding seismogram on a subset tape (not used for AEDS data).	
269	F	B factor for P_n wave for source-receiver distance (AEDS data, only).	
270	F	B factor for P wave for source-receiver distance (AEDS data, only).	
271	F	B factor for Sn wave for source-receiver distance (AEDS data, only).	
272	F	B factor for lg wave for source-receiver distance (AEDS data, only).	
273	F	B factor for long-period surface wave for source-receiver distance (AEDS data, only)	
274	I	Edit start time index into the available data (AEDS data, only).	
275-276		Available for future use.	
277-336	I	Parameters used by subroutine MSDISC (AEDS data, only).	
296-335	F	Sensor East Cartesian coordinates with respect to the reference sensor (km).	
336-375	F	Sensor North Cartesian coordinates with respect to the reference sensor (km).	

*A = Alphanumeric, I = Integer, F = Floating Point

TABLE C-3

RAW SIGNAL MEASUREMENTS

Real *4 Word	Description
	Long-Period
1	18-22 sec Vertical Log A/T *
2	50 sec Vertical Log A **
3	33.3 sec Vertical Log A
4	25 sec Vertical Log A
5	20 sec Vertical Log A
6	17 sec Vertical Log A
7	14 sec Vertical Log A
8	12 sec Vertical Log A
9	25 sec Transverse Log A
	Short-Period
10	P-wave log A/T ($\Delta<20^{o}$)
11	S-wave log A/T ($\Delta<20^{o}$)
12	Lg-wave log A/T ($\Delta<20^{o}$)
13	P-wave log A/T ($\Delta>20^{o}$)
14	0.316 Hz Vertical Log A
15	0.501 Hz Vertical Log A
16	0.794 Hz Vertical Log A
17	1.259 Hz Vertical Log A
18	1.995 Hz Vertical Log A
19	3.162 Hz Vertical Log A
20	5.012 Hz Vertical Log A
21	7.943 Hz Vertical Log A
22	Maximum mean frequency
23	Mean phase standard deviation
24	Broadband complexity
25	Minimum narrowband complexity

* Log A/T = logarithm (base 10) amplitude/period + B-factor

** Log A = logarithm (base 10) amplitude + B-factor
